# Method for Translating a Point in One Plane to Another Plane, Given a Set of Corresponding Control Points in Each Plane 

Justin A. Parr<br>q3ej7ejsjb@snkmail.com<br>http://justinparrtech.com<br>Version 1.0, 9/24/2016

## Executive Summary

Assuming that we start with a set of control points in plane $A$, and a corresponding set of control points in plane $B$, this document describes a method for translating an arbitrary point $P$ from plane $A$ to its corresponding location in plane $B$.

Plane $A$

Illustration 1: Using a set of points in Plane A, and a corresponding set of points in Plane B, Point P in Plane A is translated to its new position in Plane B

## Notation

Through the course of this document, we will be using the following notation.

| Notation | Meaning |
| :---: | :--- |
| $\ldots$ A | Line A |
| $\ldots$ PQ | Line segment formed by points P and Q |
| / a | Angle a |
| / PQR | Angle formed by line segments __ PQ and __ QR |
| P vs P' | Point P in Plane A will be notated as P, while the same point in Plane B will be notated <br> as P |
| sqrt() | Square Root function. sqrt(4) =2 |
| A * B | A multiplied by B |
| A / B | A divided by B |

## Corrected Arctangent Function

Some calculators and computers only return a result for ArcTangent in the first quadrant.

## What is ArcTangent?

Tangent is one of the three basic trig functions.

For a given angle a:

| $\sin (a)$ | $\frac{\text { opposite }}{\text { hypotenuse }}$ |
| :---: | :---: |
| $\cos (a)$ | $\frac{\text { adjacent }}{\text { hypotenuse }}$ |
| $\tan (\mathrm{a})$ | $\frac{\text { opposite }}{\text { adjacent }}$ |

ArcTangent is the inverse of the tangent function:

$$
\operatorname{atan}(o p p / a d j)=a
$$

Given a y offset and an x offset, we find the angle with:

$$
a=\operatorname{atan}(y / x)
$$

If we want to find the angle of a line connecting two points, $p_{1}$ and $p_{2}$ :

$$
\mathrm{a}=\operatorname{atan}\left(\left(\mathrm{y}_{2}-\mathrm{y}_{1}\right) /\left(\mathrm{x}_{2}-\mathrm{x}_{1}\right)\right)
$$

## The Problem With Atan and Quadrants

A circle has four quadrants:

In quadrant $\mathrm{I}, \mathrm{x}$ and y are positive. In quadrant III, x and y are negative.
Positive divided by positive yields a positive result. Likewise, a negative divided by a negative yields a positive result.

This means that, without additional information, $\operatorname{atan}(y / x)$ would have the same result in both quadrant I and III. Likewise, a result in quadrant II can't be distinguished from quadrant IV.
This means that many calculator and compiler implementations won't return a result in quadrants II or III - they simply return a result in the range of $+/-(\pi / 2)$. Worse, some compilers only operate in quadrant I, returning $0 . . \pi / 2$

## Building a Corrected Atan Function

To correct the quadrant problem, we basically have to add a bunch of if..then logic:

$$
a=\operatorname{atan}(y / x) \quad / / \text { Return a result in quadrant I: } 0 . . \pi / 2
$$

```
if y<0 then
    // Quadrants III and IV
    if x < 0 then
            // Quadrant III -x,-y; Shift result 2 quadrants
            a= a + \pi
    else
            // Quadrant IV +x,-y; Shift result 3 quadrants
            a=a+3\pi/2
    endif
else
    // Quadrants I and II
    if x}<0\mathrm{ then
            // Quadrant II -x,+y; Shift result 1 quadrant
            a = a +\pi/2
    else
            // Quadrant I +x, +y; Don't do anything
    endif
endif
```

This returns an angle a in the range of $0 . .2 \pi$
We will call our corrected function atanc - short for atan (corrected)
We will use this form to invoke our corrected atan function:

$$
\mathrm{a}=\operatorname{atanc}(\mathrm{y}, \mathrm{x})
$$

## Process Overview

## 1. In Plane A:

a) Find the two closest control points to point $P$, and label them $C_{1}$ and $C_{2}$.
b) $\mathrm{C}_{1}$ will be assigned as the pivot.
c) Find the distance $d$ between the two control points.
d) Find the distance $p$ between P and the pivot, $\mathrm{C}_{1}$.
e) Compute $r$ as the ratio of $p: d$.
f) Find the absolute angle / $a$ of line $\qquad$ $\mathrm{C}_{1} \mathrm{C}_{2}$.
g) Find the absolute angle / $b$ of line $\qquad$ $\mathrm{C}_{1} \mathrm{P}$ ( $\mathrm{C}_{1}$ is the pivot).
h) Compute relative angle $/ y$ as $/ b$ minus $/ a$. (Note that $/ y$ might be negative or positive, and represents the angular offset )

## 2. In Plane B:

a) Assign $C_{1}$ ' and $C_{2}$ ' as elements from Plane $B$ corresponding to $C_{1}$ and $C_{2}$, respectively.
b) Find the distance $d^{\prime}$ between $\mathrm{C}_{1}{ }^{\prime}$ and $\mathrm{C}_{2}{ }^{\prime}$.
c) Compute $p^{\prime}$ as $d^{\prime}$ times $r$.
d) Find absolute angle / $a$ ' of line $\quad{ }^{\prime} \mathrm{C}_{1}{ }^{\prime} \mathrm{C}_{2}{ }^{\prime}$.
e) Compute angle $/ b^{\prime}$ as $/ a^{\prime}+/ y$.
f) Compute $\mathrm{P}^{\prime}$ offset from $\mathrm{C}_{1}$ ' using a vector whose magnitude is $p$ ' and angle is / $b$ '.

## Detailed Process

Approach: We will compute $y$ and $r$ in Plane A and carry them over to Plane B. Then, we will use $y, r$, $d^{\prime}$ and $a$ ' to calculate a vector ( $p$ ' @ $b^{\prime}$ ) which determines $\mathrm{P}^{\prime}$ as an offset of $\mathrm{C}_{1}$ '.

## 1. Plane A

| Variable | Explanation |
| :---: | :--- |
| $\mathrm{C}_{1}$ | First Control point, and also the "pivot" point. $\mathrm{C}_{1}$ is located at $\left(\mathrm{X}_{1}, \mathrm{Y}_{1}\right)$ |
| $\mathrm{C}_{2}$ | Second Control point, located at $\left(\mathrm{X}_{2}, \mathrm{Y}_{2}\right)$ |
| P | Arbitrary point, located at $\left(\mathrm{X}_{\mathrm{P}}, \mathrm{Y}_{\mathrm{P}}\right)$ |
| d | Distance from $\mathrm{C}_{1}$ to $\mathrm{C}_{2}\left(\right.$ same as $\left.\mathrm{d}_{1,2}\right)$ |
| p | Distance from $\mathrm{C}_{1}$ to P |
| $a$ | Angle from normal through $\mathrm{C}_{1}$ to $\quad \mathrm{C}_{1} \mathrm{C}_{2}$ |
| $b$ | Angle from normal through $\mathrm{C}_{1}$ to $\mathrm{C}_{1} \mathrm{P}$ |
| $y$ | +/- Angle offset from / $a$ to $/ b$ |
| r | Ratio of p:d |
| $\mathrm{S}\}$ | Set of all control points in Plane A |

a) In the set of all control points $\mathrm{S}\left\}\right.$, find the two closest control points to $\mathrm{P}, \mathrm{C}_{1}$ and $\mathrm{C}_{2}$.

For each element $S_{k}$ in $S_{1 . n}$, compute $d_{k}=\operatorname{sqrt}\left(\left(X_{P}-X_{k}\right)^{2}+\left(Y_{P}-Y_{k}\right)^{2}\right)$

Assign the elements of $S$ corresponding to the two smallest values of $d_{1 . . n}$ to $C_{1}$ and $C_{2}$, respectively.
So if $\mathrm{d}_{\mathrm{k}}$ and $\mathrm{d}_{\mathrm{m}}$ are the smallest, then $\mathrm{C}_{1}=\mathrm{S}_{\mathrm{k}}$ and $\mathrm{C}_{2}=\mathrm{S}_{\mathrm{m}}$ After this point, we can effectively ignore the rest of $S\}$
b) $\mathrm{C}_{1}$ (also, $\mathrm{S}_{\mathrm{k}}$ ) is the pivot.
c) Compute d
$\mathrm{d}_{1,2}=\operatorname{sqrt}\left(\left(\mathrm{X}_{2}-\mathrm{X}_{1}\right)^{2}+\left(\mathrm{Y}_{2}-\mathrm{Y}_{1}\right)^{2}\right)$
d) p has already been computed: $\mathrm{p}=\mathrm{d}_{\mathrm{k}}$
e) Compute r
$r=p / d$
Note: $r$ is constant from Plane A to Plane B
f) Compute / $a$, the angle between $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$

$$
a=\operatorname{atanc}\left(\left(\mathrm{Y}_{2}-\mathrm{Y}_{1}\right),\left(\mathrm{X}_{2}-\mathrm{X}_{1}\right)\right)
$$

g) Compute $/ b$, the angle between $\mathrm{C}_{1}$ and P
$b=\operatorname{atanc}\left(\left(\mathrm{Y}_{\mathrm{P}}-\mathrm{Y}_{1}\right),\left(\mathrm{X}_{\mathrm{P}}-\mathrm{X}_{1}\right)\right)$
h) Compute $/ y$, the offset of angle / $a$ from angle / $b$.

$$
y=b-a
$$

Note: y is constant from Plane A to Plane B

## 2. Plane B

Plane B

| Variable | Explanation |
| :---: | :---: |
| $\mathrm{C}_{1}{ }^{\prime}$ | First Control point, and also the "pivot" point. $\mathrm{C}_{1}$ ' is located at ( $\mathrm{X}_{1}{ }^{\prime}, \mathrm{Y}_{1}{ }^{\prime}$ ) |
| $\mathrm{C}_{2}{ }^{\text {' }}$ | Second Control point, located at ( $\mathrm{X}_{2}{ }^{\prime}, \mathrm{Y}_{2}{ }^{\prime}$ ) |
| P' | The translation of P, and arbitrary point, from Plane A to Plane B |
| d' | Distance from $\mathrm{C}_{1}{ }^{\prime}$ to $\mathrm{C}_{2}{ }^{\prime}$ ( same as $\mathrm{d}_{1,2}{ }^{\prime}$ ) |
| p' | Distance from $\mathrm{C}_{1}$ ' to $\mathrm{P}^{\prime}$ |
| $a^{\prime}$ | Angle from normal through $\mathrm{C}_{1}{ }^{\prime}$ to $\ldots \mathrm{C}_{1}{ }^{\prime} \mathrm{C}_{2}{ }^{\prime}$ |
| $b^{\prime}$ | Angle from normal through $\mathrm{C}_{1}{ }^{\prime}$ to $\mathrm{C}_{1}{ }^{\prime} \mathrm{P}$ ' |
| $y$ | +/- Angle offset from / $a$ to / bin Plane A, and / $a^{\prime}$ 'to / b' in Plane B |
| r | Ratio of p:d in Plane A, and p':d' in Plane B |
| S' $\{$ \} | Set of all control points in Plane B. Each $\mathrm{S}_{1 . . n}$ in Plane A corresponds to $\mathrm{S}_{1 . . n}$ ' in Plane B |

a) Assign corresponding elements from $S^{\prime}\{ \}$ from Plane $B$ to $C_{1}{ }^{\prime}$ and $C_{2}{ }^{\prime}$.

Recalling that
$\mathrm{C}_{1}=\mathrm{S}_{\mathrm{k}}$ and $\mathrm{C}_{2}=\mathrm{S}_{\mathrm{m}}$
Then,
$\mathrm{C}_{1}{ }^{\prime}=\mathrm{S}_{\mathrm{k}}{ }^{\prime}$
and
$\mathrm{C}_{2}{ }^{\prime}=\mathrm{S}_{\mathrm{m}}{ }^{\prime}$
b) Compute d’

$$
\mathrm{d}_{1,2^{\prime}}=\operatorname{sqrt}\left(\left(\mathrm{X}_{2}^{\prime}-\mathrm{X}_{1}{ }^{\prime}\right)^{2}+\left(\mathrm{Y}_{2}^{\prime}-\mathrm{Y}_{1}{ }^{\prime}\right)^{2}\right)
$$

c) Compute $p$ 'using $r$, the ratio of $\mathrm{d}: p$

$$
\mathrm{p}^{\prime}=\mathrm{d}^{\prime} * \mathrm{r}
$$

d) Compute $a$,

$$
a^{\prime}=\operatorname{atanc}\left(\left(\mathrm{Y}_{2}^{\prime}-\mathrm{Y}_{1}{ }^{\prime}\right),\left(\mathrm{X}_{2}^{\prime}-\mathrm{X}_{1}^{\prime}{ }^{\prime}\right)\right)
$$

e) Compute $b$ ' from $a$ ' and $y$. Note that $y$ is an angular offset, +/- from $a$.

$$
b^{\prime}=a^{\prime}+y
$$

f) Compute $P^{\prime}$ from $C_{1}$ plus a vector whose magnitude is $p$ ' and angle is / $b$ '

$$
\begin{aligned}
& \mathrm{X}_{\mathrm{P}}^{\prime}=\mathrm{X}_{1}^{\prime}+p^{\prime} * \cos \left(b^{\prime}\right) \\
& \mathrm{Y}_{\mathrm{P}}^{\prime}=\mathrm{Y}_{1}^{\prime}+p^{\prime} * \sin \left(b^{\prime}\right)
\end{aligned}
$$

$P^{\prime}$ is located at $\left(X_{P}{ }^{\prime}, Y_{P}{ }^{\prime}\right)$

## Limitations

Plane $A$

Plane B

In this example, the two closest control points to P don't move, but a third control point moves significantly. The resulting position for $P^{\prime}$ in Plane B is identical to the position of P, but doesn't take in to account the final position of control point $\mathrm{C}_{3}$.

In this situation, knowing that $C_{3}$ ' is closer in Plane $B$ than either $C_{1}$ ' or $C_{2}$ ', we could go back to Plane A and average the result of translating $P$ using each set:

- $\mathrm{C}_{1}, \mathrm{C}_{2}$
- $\mathrm{C}_{2}, \mathrm{C}_{3}$
- $\mathrm{C}_{1}, \mathrm{C}_{3}$

Further, having many more control points yields more accurate translation results.

## Conclusion

This method provides a simple method to translate an arbitrary point from Plane A to Plane B using a network of control points.

A practical application for this process, is to dynamically translate an arbitrary location between virtual and physical coordinates based on a set of landmarks.
